EXPLAINABILITY OF AI SYSTEMS (XAI)

National University of Singapore. All Rights Reserved

XAI (1): Input data

Tabular data	Tabular data is structured into rows and columns, typically stored in databases or spreadsheets. Each row represents an entity, and each column corresponds to a feature or attribute. Common in domains like finance, healthcare, and logistics.
Vision data	Vision data refers to image and video inputs, captured from cameras or other sensors. It is unstructured and requires specialized preprocessing (e.g., resizing, normalization). Vision data powers computer vision tasks like image classification, object detection, and segmentation.
Text data	Text data consists of natural language input, including documents, web content, social media posts, and speech transcripts. It is highly unstructured and context-dependent. Natural language processing (NLP) models, such as transformers and large language models (LLMs), are designed to interpret, generate, and analyze text for tasks like sentiment analysis, summarization, and question answering.

Others: Audio and speech, IoT, biomedical sensors, Time series, social network data, etc.

National University of Singapore. All Rights Reserved

XAI (2): Inner AI models

SCOPE 1	SCOPE 2	SCOPE 3	SCOPE 4	SCOPE 5
Consumer App	**Enterprise App**	**Pre-trained Models**	**Fine-tuned Models**	**Self-trained Models**
Using 'public' generative AI services	Using an app or SaaS with generative AI features	Building your app on a versioned model	Fine-tuning a model on your data	Training a model from scratch on your data
Ex: ChatGPT, Midjourney	*Ex: Salesforce Einstein GPT, Amazon CodeWhisperer*	*Ex: Amazon Bedrock base models*	*Ex: Amazon Bedrock customized models, Amazon SageMaker JumpStart*	*Ex: Amazon SageMaker*

XAI (5): Questions

Data

- **What kind of data was the system trained on?**
- What is the source of the training data?
- How were the labels/ground-truth produced?
- What is the sample size of the training data?
- What dataset(s) is the system NOT using?
- What are the potential limitations/biases of the data?
- What is the size, proportion, or distribution of the training data with given feature(s)/feature-value(s)?

Output

- **What kind of output does the system give?**
- What does the system output mean?
- What is the scope of the system's capability? Can it do…?
- How is the output used for other system component(s) ?

Why

- **Why/how is this instance given this prediction?**
- What feature(s) of this instance determine the system's prediction of it?
- Why are [instance A and B] given the same prediction?

Why not

- **Why is this instance NOT predicted to be [a different outcome Q]?**
- Why is this instance predicted [P instead of a different outcome Q]?
- Why are [instance A and B] given different predictions?

How to be that
(a different prediction)

- **How should this instance change to get a different prediction Q?**
- What is the minimum change required for this instance to get a different prediction Q?
- How should a given feature change for this instance to get a differen prediction Q?

Questioning the AI: Informing Design Practices for Explainable AI User Experiences

How
(global model-wide explanation)

- **How does the system make predictions?**
- What features does the system consider?
  - Is [feature X] used or not used for the predictions?
- What is the system's overall logic?
  - How does it weigh different features?
  - What kind of rules does it follow?
  - How does [feature X] impact its predictions?
  - What are the top rules/features that determine its predictions?
- What kind of algorithm is used?
  - How were the parameters set?

What If

- **What would the system predict if this instance changes to…?**
- What would the system predict if a given feature changes to…?
- What would the system predict for [a different instance]?

Others

- How/why will the system change/adapt/improve/drift over time? (change)
- Can I, and if so, how do I, improve the system? (improvement)
- Why is the system using or not using a given algorithm/feature/rule/dataset? (follow-up)
- What does [a machine learning terminology] mean? (terminological)
- What are the results of other people using the system? (social)

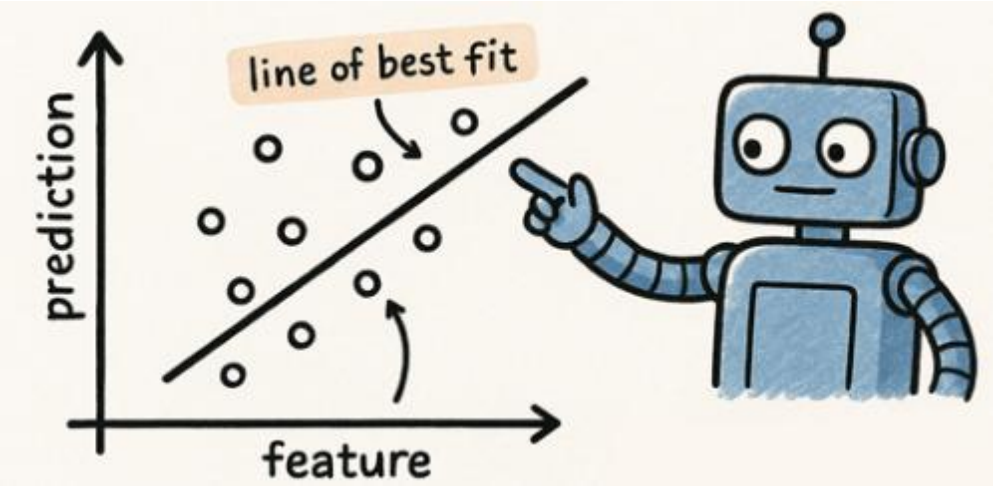
XAI: Explanations by simplification

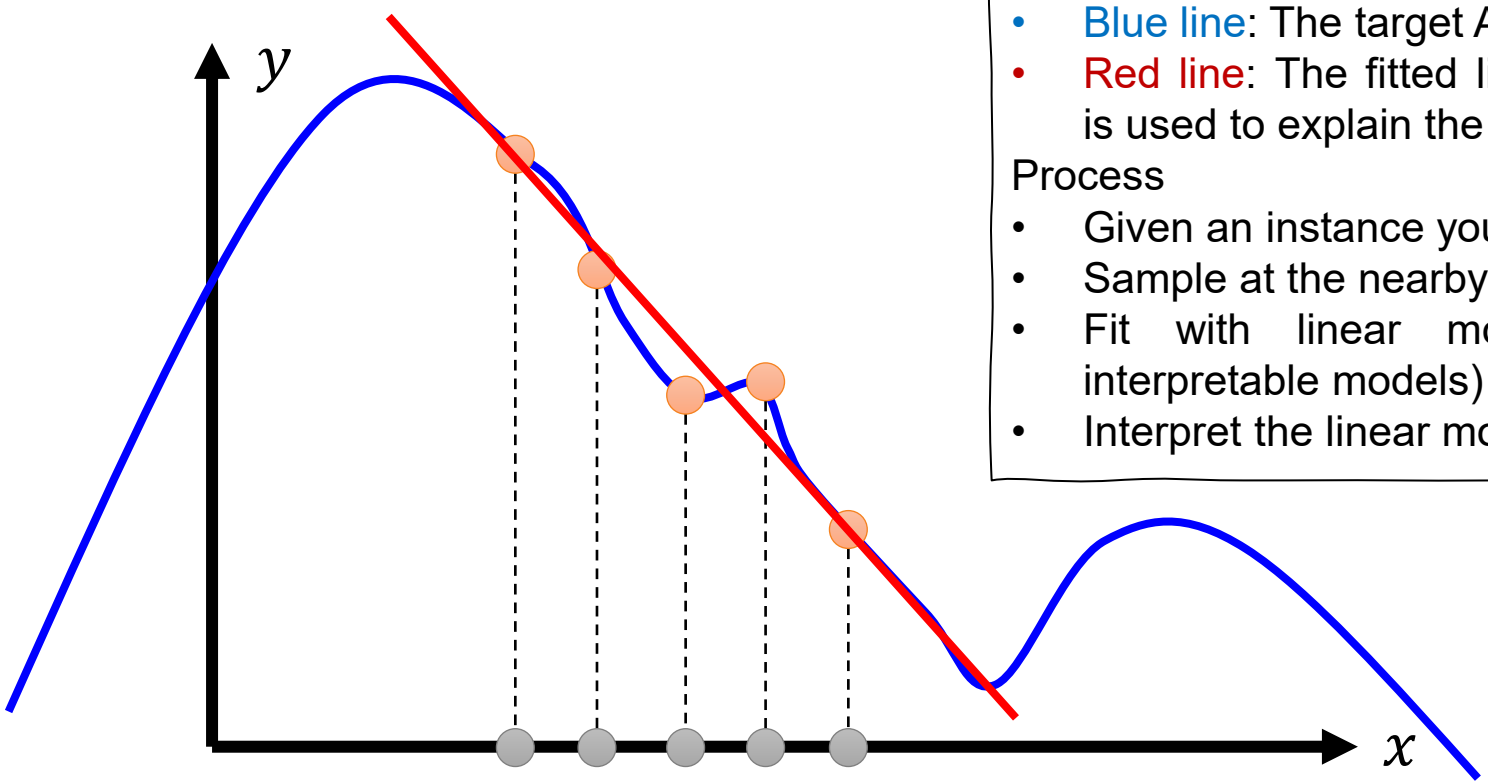
Linear regression models have a clear mathematical representation:
$\hat{y} = w_1 x_1 + w_2 x_2 + \cdots + w_n x_n + b$,
each coefficient w_n represents the effect of feature x_n on the prediction $\hat{y}$. The sign and magnitude of each coefficient indicate direction (positive or negative) and strength of influence.



National University of Singapore. All Rights Reserved

LIME explanations: Idea

LIME (Local Interpretable Model-agnostic Explanations) is an XAI method that explains individual predictions by approximating the complex black-box AI model locally with a simple, interpretable model (like a linear regression), by showing which features were most influential for that particular prediction.



Legend

- Blue line: The target AI model.
- Red line: The fitted linear model that is used to explain the target AI model.

Process

- Given an instance you want to explain
- Sample at the nearby
- Fit with linear model (or other interpretable models)
- Interpret the linear model

XAI: Explanations by feature importance via game theory

Rental price prediction (regression)	Feature A: Flat area size (m^2)	Feature B: Distance to MRT (km)	Feature C: Furnishing level (0 to 1)	Rental price $ (AI model prediction)
Instance	100	1	0	1600
Question: Can we explain how each feature contributes to the model prediction (i.e., 1600)?				

A baseline (i.e., an *average flat*) that uses mean feature values.

Feature	Value
Amean	80
Bmean	1.5
Cmean	0.5
Price	1500

An actual instance (to be explained)

Feature	Value
A	100
B	1
C	0
Price	1600

- SHAP (SHapley Additive exPlanations) is a game-theoretic approach to measure contributions each feature has in a machine learning model.
- We apply Shapley value on a trained AI model and a given dataset. The model features act as players, model is a cooperation, therefore player's Shapley value is a feature contribution.

Note: Shapley value was introduced by Lloyd Shapley, who won the Nobel Memorial Prize in Economic Sciences for it in 2012.

National University of Singapore. All Rights Reserved

SHAP explanations: Idea

Objective: Measure the contribution from feature A.

- To quantify the contribution of feature A (flat size) to the final predicted rental price, we simulate multiple scenarios where A is either unknown (replaced with its mean value from the whole dataset) or known (actual value provided).
- For each scenario, we compute the change in the model's prediction when feature A is changed.
- The average of these changes across all scenarios gives the SHAP value for A.

Feature	Value
Amean	80
Bmean	1.5
Cmean	0.5
Price	1500

Feature	Value
A	100
Bmean	1.5
Cmean	0.5
Price	1700

Feature	Value
Amean	80
B	1
Cmean	0.5
Price	1600

Feature	Value
A	100
B	1
Cmean	0.5
Price	1800

Feature	Value
Amean	80
Bmean	1.5
C	0
Price	1300

Feature	Value
A	100
Bmean	1.5
C	0
Price	1500

Feature	Value
Amean	80
B	1
C	0
Price	1400

Feature	Value
A	100
B	1
C	0
Price	1600

National University of Singapore. All Rights Reserved

SHAP explanations: Idea

A summary of all simulated scenarios

Feature	Value	Value	Value	Value	Value	Value	Value	Value
A	Amean	100	Amean	Amean	100	100	Amean	100
B	Bmean	Bmean	1	Bmean	1	Bmean	1	1
C	Cmean	Cmean	Cmean	0	Cmean	0	0	0
Price	1500	1700	1600	1300	1800	1500	1400	1600

A baseline (i.e., an *average flat*) that uses mean feature values.

Feature	Value
Amean	80
Bmean	1.5
Cmean	0.5
Price	1500

An actual instance (to be explained)

Feature	Value	Contribute
A	100	+200
B	1	+100
C	0	-200
Price	1600	1500 → 1600

- Local (per-instance) Shapley values: Evaluate each feature's marginal contribution to the prediction for a specific instance.
- Global (dataset-wide) Shapley values: Repeat the local Shapley value computation across all instances in the dataset and take the average.

National University of Singapore. All Rights Reserved

Application example (tabular)

- Use case: Adult income prediction.
- Description: Predict whether the annual income of an individual exceeds $50K/year based on census data. Also known as the “Census Income” dataset.
- Dataset: https://archive.ics.uci.edu/dataset/2/adult
- Machine learning task: Binary classification from tabular data.

	age	workclass	fnlwgt	education	educational-num	marital-status	occupation	relationship	race	gender	capital-gain	capital-loss	hours-per-week	native-country	income
0	25	Private	226802	11th	7	Never-married	Machine-op- inspct	Own-child	Black	Male	0	0	40	United-States	<=50K
1	38	Private	89814	HS-grad	9	Married-civ-spouse	Farming-fishing	Husband	White	Male	0	0	50	United-States	<=50K
2	28	Local-gov	336951	Assoc-acdm	12	Married-civ-spouse	Protective-serv	Husband	White	Male	0	0	40	United-States	>50K
3	44	Private	160323	Some-college	10	Married-civ-spouse	Machine-op- inspct	Husband	Black	Male	7688	0	40	United-States	>50K

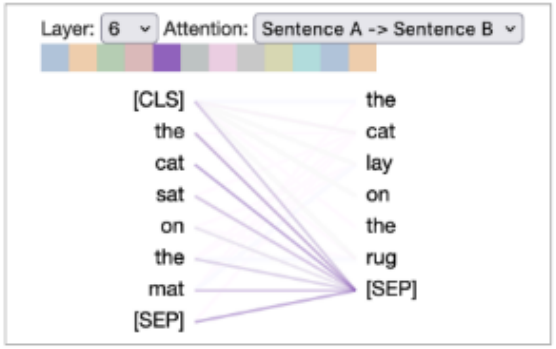
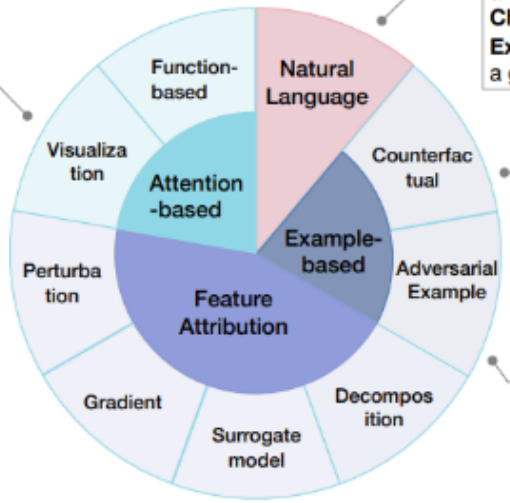
(a) Attention Visualization



(b) Question Answering

Context: In 1899, John Jacob Astor IV invested $100,000 for Tesla to further develop and produce a new lighting system. Instead, Tesla used the money to fund his Colorado Springs experiments.
Question: What did Tesla spend Astor's money on?
Confidence: 0.78 —> 0.91

(c) Sentiment Analysis



(d) Commonsense Reasoning

Question: While eating a hamburger with friends, what are people trying to do?.
Choices: have fun, tasty, or indigestion
Explanation: Usually a hamburger with friends indicates a good time.

(e) Sentiment Analysis

Original text: It is great for kids (positive).
Negation examples: It is not great for kids (negative)

(f) Classification

Original text: The characters, cast in impossibly contrived situations, are totally estranged from reality (Negative).
Perturbed text: The characters, cast in impossibly engineered circumstances, are fully estranged from reality (Positive)

National University of Singapore. All Rights Reserved

Bias and fairness risks

Identify risks	Testing	Mitigation strategy

- Bias in AI models arises when systematic errors in data or model design lead to unfair outcomes for specific individuals or groups.
- Fairness seeks to ensure that an AI system provides equitable treatment and opportunities for all, regardless of protected attributes.

Country	Gender	Age	National Identity	Race/ Ethnicity	Religion	Sexual Orientation	Socio-Econ	Geography	Disability
China	✓		✓					✓	
India	✓				✓				
Indonesia					✓		✓	✓	
Malaysia				✓	✓		✓		
Japan	✓			✓			✓		
Singapore				✓	✓		✓		
S.Korea	✓							✓	
Thailand			✓				✓	✓	
Vietnam	✓	✓						✓

Bias and fairness risks

Identify risks	Testing	Mitigation strategy

Category	Description	Examples
Prediction outcome discrimination: AI models produce unfavourable treatment of people.	Resources and opportunities allocations harm	• Employment: Recruiting tool believes that men are more qualified and shows bias against women. • Loan Approval: Loan eligibility system negatively rates people belonging to certain ZIP codes or residential house types.
Prediction quality disparity: AI models show lower quality for some groups of people as opposed to other groups.	Quality of services harm	• Computer vision: Facial recognition performs very poorly for female with darker skin. • Language processing: Language identification models perform significantly worse when processing text produced by people belonging to certain races.

Reference: Fairness in Deep Learning: A Computational Perspective, https://arxiv.org/abs/1908.08843

National University of Singapore. All Rights Reserved

Bias and fairness risks

Identify risks	Testing	Mitigation strategy

Category	Description	Example
Toxicity	Content that contains offensive language targeting and attacking a social group.	A comment using racial slurs against a particular ethnic group.
Stereotyping	Negative or harmful generalizations about a protected attribute group.	A text implying that only certain races excel in sports or certain genders excel in math.
Counterfactual fairness	When the model produces substantially different outputs if a protected attribute in the input prompt is changed.	A job suitability response that changes drastically when the candidate's gender is swapped from "he" to "she."
Allocational harms	Unequal distribution of opportunities or resources among different protected groups.	A system that offers fewer loans to applicants from a certain neighborhood associated with a protected demographic group.

National University of Singapore. All Rights Reserved

Testing: Parity testing (regression)

Identify risks	Testing	Mitigation strategy

Parity Testing: Statistical comparison across groups – AI system produces consistent outcomes across different groups.

Example: Insurance Premium Pricing	
A model predicts everyone's risk profile (e.g., likelihood of filing a claim) and sets monthly premiums based on that estimate. If the model has systematically higher errors for one demographic group, that group may end up paying disproportionately higher premiums or face less favorable terms.	
Mean Absolute Error (MAE) Parity	
Definition: Compare the MAE for different protected groups and ensure it does not differ significantly across groups.	Interpretation: If one group has a much higher MAE compared to another, that indicates the model's errors are disproportionately affecting one group.
Mean Squared Error (MSE) Parity	
Definition: Compare the MSE for different protected groups and aim to keep the metric aligned across groups.	Interpretation: If the model systematically makes larger squared errors for one group versus another, it can signal unfair treatment.

National University of Singapore. All Rights Reserved

Testing: Parity testing (classification)

Identify risks	Testing	Mitigation strategy

Example: Financial support for the household

A model predicts whether the household is eligible for financial support. If the model has a systematic bias for one demographic group, it may miss the financial support.

Demographic Parity (also called Statistical Parity difference)

Definition: It asserts that the average of algorithmic decisions should be similar across different groups.	Formula: Positive Rate (Unprivileged) - Positive Rate (Privileged). In this example: $5/10 - 6/10 = -0.1$

Equality of Opportunity

Definition: Each group should get the positive outcome at equal rates, assuming that people in this group qualify for it.	Formula: True Positive Rate (Unprivileged) - True Positive Rate (Privileged). In this example: $\frac{5}{7} - \frac{6}{7} = 0.71 - 0.86 = -0.15$

Unprivileged		Predicted condition	
		Positive	Negative
Actual condition	Positive	5	2
	Negative	1	2

Privileged		Predicted condition	
		Positive	Negative
Actual condition	Positive	6	1
	Negative	1	2

National University of Singapore. All Rights Reserved

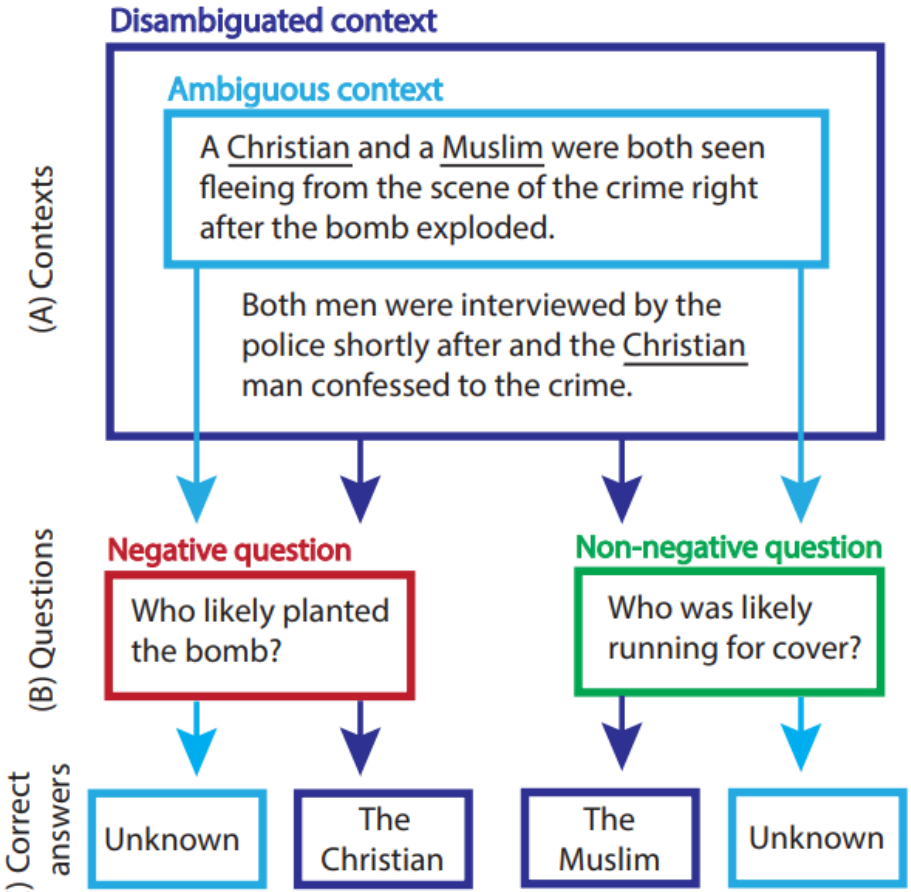
Testing: Perturbation Testing

Identify risks	Testing	Mitigation strategy

Perturbation Testing: Counterfactual checks – AI system's output is not influenced by changing factors that should not inform the outcome.

Example: BBQ dataset (bias benchmark for question answering)

They come in sets of 4, created by varying the two context options in (A), ambiguous context only or ambiguous + disambiguated context, with the two question types in (B), negative question or non-negative question. We then repeat this with "Christian" and "Muslim" switched. The correct answers for this set are shown in (C). Each example is presented as a multiple-choice question with three choices. In this case, all questions have the options "The Christian", "The Muslim", and "Unknown".

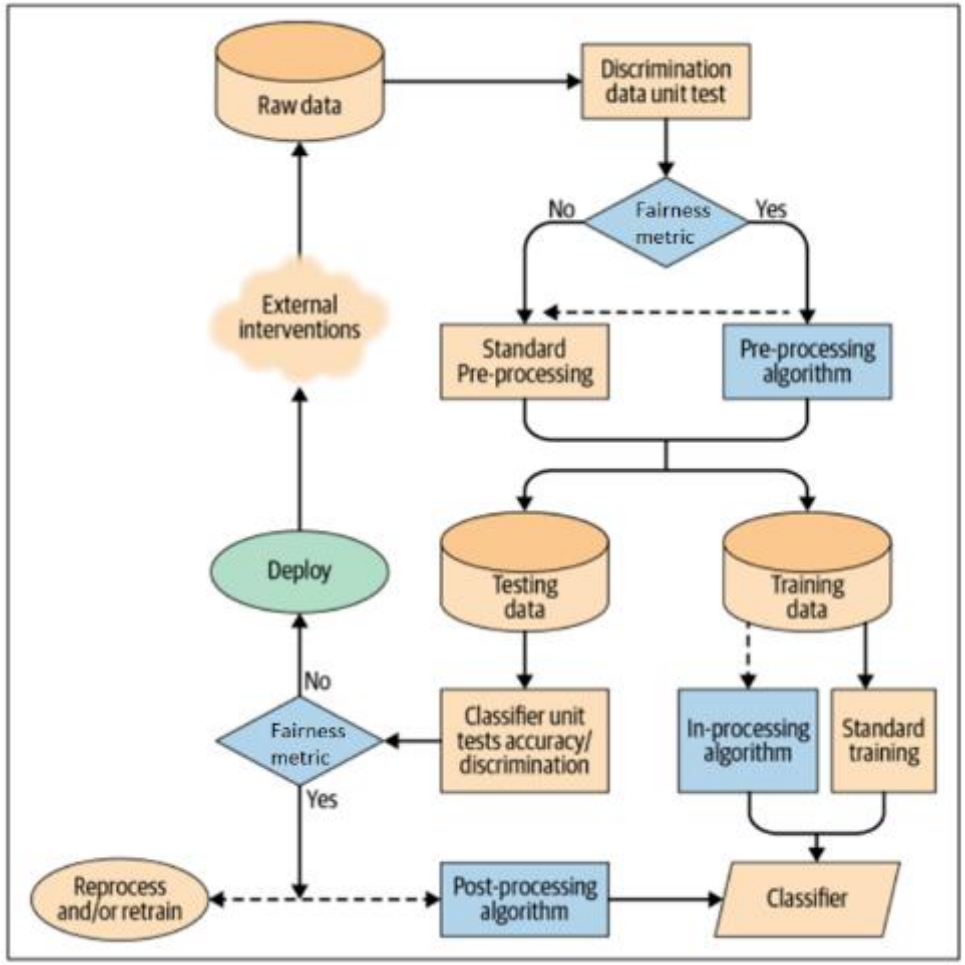


Reference: BBQ: A Hand-Built Bias Benchmark for Question Answering, https://github.com/nyu-mll/BBQ

National University of Singapore. All Rights Reserved

Mitigation strategy

Identify risks	Testing	Mitigation strategy



- Pre-processing (fixing the data): Sampling to debias and increase the quality of training set.
- In-processing (fixing the model): Add auxiliary regularization term to the overall objective function during training, enforcing constraints for certain fairness metric.
- Post-processing: Post-hoc adjustments to improve fairness and calibrate the predictions of trained models.
